School of Electrical Engineering, Electronics, and Computer Science
University of Liverpool

Classes Defining and Instantiating a Class

A Closer Look at Class Definitions

- The pseudo-variable `$this` is available when a method is called from within an object context and is a reference to the calling object
- Inside method definitions, `$this` can be used to refer to the properties and methods of the calling object
- The **object operator** `->` is used to access methods and properties of the calling object

```
class Rectangle {
    protected $height;
    protected $width;

    function __construct($height,$width) {
        $this->width = $width;
        $this->height = $height;
    }
}
```

COMP284 Scripting Languages

Lecture 13

Slide L13 – 4

Contents

- 1 Classes
 - Defining and Instantiating a Class
 - Visibility
 - Class Constants
 - Static Properties and Methods
 - Destructors
 - Inheritance
 - Interfaces
 - Introspection Functions
- 2 The PDO Class
 - Introduction
 - Connections
 - Queries and Processing of Results
 - Prepared Statements

Classes

Visibility

Visibility

- Properties and methods can be declared as
 - public** accessible everywhere
 - private** accessible only within the same class
 - protected** accessible only within the class itself and by inheriting and parent classes

- For **properties**, a **visibility** declaration is required
- For **methods**, a **visibility** declaration is optional
 - ~ by default, **methods** are **public**
- Accessing a **private** or **protected** property /

```
class Vis {
    public $public = 1;
    private $private = 2;
    protected $protected = 3;
    protected function proFc() {}
    private function priFc() {}
}

$v = new Vis();
echo $v->public; # prints 1
echo $v->private; # Fatal Error
echo $v->protected; # Fatal Error
echo $v->priFc(); # Fatal Error
echo $v->proFc(); # Fatal Error
```

COMP284 Scripting Languages

Lecture 13

Slide L13 – 5

Defining and Instantiating a Class

- PHP is an object-oriented language with **classes**
- A **class** can be defined as follows:

```
class identifier {
    property_definitions
    function_definitions
}
```
- The **class name** *identifier* is **case-sensitive**
- The body of a class consists of **property definitions** and **function definitions**
- The function definitions may include the definition of a **constructor**
- An **object** of a class is created using

```
new identifier(arg1,arg2,...)
```

where `arg1,arg2,...` is a possibly empty list of arguments passed to the constructor of the class *identifier*

COMP284 Scripting Languages

Lecture 13

Slide L13 – 2

Constants

vis const identifier = value;

- Accessing a **private** or **protected** constant outside its visibility is a **fatal error** ~ execution of the script stops
- Class constants are allocated once per class, and not for each class instance
- Class constants are accessed using the **scope resolution operator** `::`:

```
class MyClass {
    const SIZE = 10;
}

echo MyClass::SIZE; # prints 10
$o = new MyClass();
echo $o::SIZE; # prints 10
```

COMP284 Scripting Languages

Lecture 13

Slide L13 – 6

Classes Defining and Instantiating a Class

A Closer Look at Class Definitions

In more detail, the definition of a **class** typically looks as follows

```
class identifier {
    # Properties
    vis $attrib1
    ...
    vis $attribN = value

    # Constructor
    function __construct(p1,...) {
        statements
    }

    # Methods
    vis function method1(p1,...) {
        statements
    }
    vis function methodN(p1,...) {
        statements
    }
}
```

- Every instance obj of this class will have **attributes** `attrib1,...` and **methods** `method1(),...` accessible as `obj->attrib1` and `obj->method1(a1,...)`
- **__construct** is the **constructor** of the class and will be called whenever **new identifier(a1,...)** is executed
- **vis** is a declaration of the **visibility** of each attribute and method

COMP284 Scripting Languages

Lecture 13

Slide L13 – 3

Classes

Static Properties and Methods

Static Properties and Methods

- **Class properties** or **methods** can be declared **static**
- Static class properties and methods are accessed (via the class) using the **scope resolution operator** `::`
- Static class **properties** cannot be accessed via an instantiated class object, but **static class methods** can
- Static class **method** have no access to `$this`

```
class Employee {
    static $totalNumber = 0;
    public $name;

    function __construct($name) {
        $this->$name = $name;
        Employee::$totalNumber++;
    }
}

$e1 = new Employee("Ada");
$e2 = new Employee("Ben");
echo Employee::$totalNumber # prints 2
```

COMP284 Scripting Languages

Lecture 13

Slide L13 – 7

Classes Destructors

Destructors

- A class can have a **destructor method** `__destruct` that will be called as soon as there are no other references to a particular object

```
class Employee {
    static $totalNumber = 0;
    public $name;

    function __construct($name) {
        $this->name = $name;
        Employee::$totalNumber++;
    }
    function __destruct() {
        Employee::$totalNumber--;
    }
}
$e1 = new Employee("Ada");
$e2 = new Employee("Ben");
echo Employee::$totalNumber # prints 2
$e1 = null;
echo Employee::$totalNumber # prints 1
```

COMP284 Scripting Languages Lecture 13 Slide L13 – 8

Classes Introspection Functions

Introspection Functions

There are functions for inspecting objects and classes:

```
bool class_exists(string $class)
returns TRUE iff a class class exists
class_exists('Rectangle') # returns TRUE
string get_class(object $obj)
returns the name of the class to which an object belongs
get_class($sq1) # returns 'Square'
bool is_a(object $obj, string $class)
returns TRUE iff obj is an instance of class named class
is_a($sq1, 'Rectangle') # returns TRUE
bool method_exists(object $obj, string $method)
returns TRUE iff obj has a method named method
method_exists($sq1, 'area') # returns TRUE
```

COMP284 Scripting Languages Lecture 13 Slide L13 – 12

Classes Inheritance

Inheritance

- In a class definition it is possible to specify one **parent class** from which a class inherits constants, properties and methods:

```
class identifier1 extends identifier2 { ... }
```
- The constructor of the parent class is **not** automatically called it must be called explicitly from the child class
- Inherited constants, properties and methods can be **overridden** by redeclaring them with the same name defined in the parent class
- The declaration **final** can be used to prevent a method from being overridden
- Using **parent::** it is possible to access overridden methods or static properties of the parent class
- Using **self::** it is possible to access static properties and methods of the current class

COMP284 Scripting Languages Lecture 13 Slide L13 – 9

Classes Introspection Functions

Introspection Functions

There are functions for inspecting objects and classes:

```
bool property_exists(object $obj, string $property)
returns TRUE iff object has a property named property
property_exists($sq1, 'size') # returns FALSE
get_object_vars(object $obj)
returns an array with the accessible non-static properties of object mapped to their values
get_object_vars($e2)
# returns ["name" => "Ben"]
get_class_methods(class $class)
returns an array of method names defined for class
get_class_methods($square)
# returns ["__construct", "area"]
```

COMP284 Scripting Languages Lecture 13 Slide L13 – 10

Classes Inheritance

Inheritance: Example

```
class Rectangle {
    protected $height;
    protected $width;

    function __construct($height, $width) {
        $this->width = $width;
        $this->height = $height;
    }
    function area() {
        return $this->width * $this->height;
    }
}

class Square extends Rectangle {
    function __construct($size) {
        parent::__construct($size, $size);
    }
}

$r1 = new Rectangle(3,4);
echo "\$r1 area = ", $r1->area(), "\n";
$s1 = new Square(5);
echo "\$s1 area = ", $s1->area(), "\n";

$r1 area = 12
$s1 area = 15
```

COMP284 Scripting Languages Lecture 13 Slide L13 – 10

The PDO Class

- The **PHP Data Objects** (PDO) extension defines an **interface** for accessing databases in PHP
- Various **PDO drivers** implement that interface for specific database management systems
 - PDO_MYSQL** implements the PDO interface for MySQL 3.x to 5.x
 - PDO_SQLSRV** implements the PDO interface for MS SQL Server and SQL Azure

COMP284 Scripting Languages Lecture 13 Slide L13 – 14

Classes Interfaces

Interfaces

- Interfaces** specify which methods a class must implement without providing an implementation
- Interfaces** are defined in the same way as a class with the keyword **class** replaced by **interface**
- All methods in an interface must be declared **public**
- A class can declare that it implements one or more interfaces using the **implements** keyword

```
interface Shape {
    public function area();
}
class Rectangle implements Shape {
    ...
}
```

COMP284 Scripting Languages Lecture 13 Slide L13 – 11

The PDO Class Connections

Connections

- Before we can interact with a DBMS we need to establish a **connection** to it
- A connection is established by **creating an instance** of the **PDO class**
- The **constructor** for the **PDO class** accepts arguments that specify the database source (DSN), username, password and additional options

```
$pdo = new PDO($dsn, $username, $password, $options);
```
- Upon successful connection to the database, the constructor returns an instance of the PDO class
- The connection remains **active** for the lifetime of that PDO object
- Assigning **NULL** to the variable storing the PDO object destroys it and **closes the connection**

```
$pdo = NULL
```
